Elliptic Curve Cryptography

an introduction which is entirely too short

by Giacomo Fenzi (ETH Zurich)
on 6 January 2022

» Motivation

'It is possible to write endlessly on elliptic curves.
(This is not a threat.)' Serge Lang

- Elliptic curves are everywhere in cryptography
- Coolest post quantum cryptography proposal
- Maths is banging

» Diophantine Equations

Historically originated in the context of solving Diophantine equations such as

$$X^n + Y^n = Z^n, \;\; X, Y, Z \in \mathbb{Z}$$

or equivalently

$$x^n + y^n = 1, \;\; x, y \in \mathbb{Q}$$

Often very hard, and in general undecidable[1]!
Let us see what we can do...

[1] In fact, already undecidable with 11 integers variables!

One variable

$$a_n x^n + a_{n-1} x^{n-1} + \dots a_1 x + a = 0$$

Quite easy! We can show that:

Theorem

Let $\frac{p}{q} \in \mathbb{Q}$ be a solution of the above equation. Then q divides a_n and p divides a_0.

Check the finite list of candidates.
Alternatively, solve numerically and find candidate of form $\frac{b}{a_n}$

» Linear and Quadratic

$$ax + by = c$$

Theorem

Has infinitely many rational solution. If $\gcd(a, b)$ *does not divide* c*, then no integers solutions. Else, infinitely many.*

$$ax^2 + bxy + cy^2 + dx + ey + f = 0$$

These are rational points on a conic.

- Given a rational point, all of them can be found geometrically
- Hasse principle allows us to test if a rational point exists

» Cubics

What about:

$$ax^3 + bx^2y + cxy^2 + dy^3 + ex^2 + fxy + gy^2 + hx + iy + j = 0\ ?$$

This is the general form of an elliptic curve! We have that

Theorem (Mordell)

If the curve is non singular, and it has a rational point then the group of rational points is finitely generated

But no equivalent of Hasse principle!

Elliptic Curves $\neq$ **Ellipse**

» Fields

Definition

A field $\mathbb{F}$ is set together with two operations $+, \cdot$ such that

* $\mathbb{F}$ is an abelian group under $+$ with identity 0
* $\mathbb{F} - \{0\}$ is an abelian group under multiplication with identity 1.
* For every $a, b, c \in \mathbb{F}$ we have that $a(b+c) = ab + ac$
* $0 \neq 1$

Informally, we can add, subtract, multiply and divide non zero elements.

» Finite Fields

We are mostly interested in finite fields. We have that:

Theorem

For every prime p, and every $n \in \mathbb{Z}^+$ there is an unique field of size p^n, which we denote by either $\mathbb{GF}(p^n)$ or $\mathbb{F}_{p^n}$

If $n = 1$, then $\mathbb{F}_p = \mathbb{Z}_p$, if not we can write them as

$$\mathbb{F}_{p^n} = \frac{\mathbb{F}_p[X]}{(f(x))}$$

where $f(x)$ is an irreducible polynomial of degree n.

» Characteristic

For any field, $\mathrm{char}(\mathbb{F})$ is the least integer[2] ℓ such that

$$\underbrace{1 + \ldots 1}_{\ell \text{ times}} = 0$$

We have that $\mathrm{char}(\mathbb{F}_{p^n}) = p$.

[2] Or ∞ if no such integer exists

» Field Extensions

Let k, K be two fields. If there is an homomorphism $k \to K$, we can identify k with a subfield of K. In that case, K is a **field extension** of k which we denote by $k \subseteq K$.
Given any field K we can construct the algebraic closure $\overline{K}$ which is the smallest algebraically closed extension containing K.
Some examples:

* $\mathbb{Q} \subseteq \mathbb{R} \subseteq \mathbb{C}$
* $\mathbb{F}_p \subseteq \mathbb{F}_{p^2} \subseteq \mathbb{F}_{p^3} \cdots \subseteq \overline{\mathbb{F}}_p$

» Weierstrass Form

$$ax^3 + bx^2y + cxy^2 + dy^3 + ex^2 + fxy + gy^2 + hx + iy + j = 0$$

$$\downarrow$$

$$y^2 + axy + by = x^3 + cx^2 + dx + e$$

$$\Big\downarrow \ \mathrm{char}(\mathbb{F}) \neq 2, 3$$

$$y^2 = x^3 + ax + b$$

Much easier to manage!

» Elliptic Curves

Definition

Let $\mathbb{F}$ be a field. An elliptic curve E defined over a field $\mathbb{F}$ (denoted by $E/\mathbb{F}$) is given by

$$E : y^2 = x^3 + ax + b$$

for $a, b \in \mathbb{F}$. For any extension $\mathbb{F} \subseteq \mathbb{E}$ we define

$$E(\mathbb{E}) = \left\{(x, y) \in \mathbb{E} \times \mathbb{E} \mid y^2 = x^3 + ax + b\right\} \cup \{\infty\}$$

Mathematicians are often interested with $E(\mathbb{Q}) \subseteq E(\mathbb{R}) \subseteq E(\mathbb{C})$ but we mostly consider the finite case.

» Some elliptic curves (In $E(\mathbb{R})$ since they look better...)

TODO: One singular with cusp, one node and three non singular

» Fundamental Quantities

Definition

Let $E : y^2 = x^3 + ax + b$ be an elliptic curve.
The **discriminant** of E is

$$\Delta = -16(4a^3 + 27b^2)$$

A curve is **singular** if $\Delta = 0$.
If E is non-singular the j-**invariant** of E is

$$j(E) = -1728\frac{(4A)^3}{\Delta}$$

Theorem

Let E, E' be two elliptic curves over K. Then $E \cong E'$ if and only if $j(E) = j(E')$.

» The Group Law

TODO: Picture group law

» The Group Law: Formulae

Let $E : y^2 = x^3 + ax + b$ be an elliptic curve. Let $P_i = (x_i, y_i) \in E(K)$. Define

$$-P_0 = (x_0, -y_0)$$

Now, for $P_1 + P_2$:

* If $x_1 = x_2$ and $y_1 = -y_2$, then $P_1 + P_2 = \infty$
* If $P_1 = \infty$ then $P_1 + P_2 = P_2$, and viceversa.
* Let $x_3 = \lambda^2 - x_1 - x_2$, $y_3 = \lambda(x_1 - x_3) - y_1$ where λ is defined as:

$$\lambda = \begin{cases} \frac{y_2 - y_1}{x_2 - x_1}, & x_1 \neq x_2 \\ \frac{3x_1^2 + a}{2y_1}, & \text{otherwise} \end{cases}$$

This makes E into an abelian group with identity ∞

» Scalar multiplication

For $n > 0, P \in E$ we write $[n]P = \underbrace{P + \cdots + P}_{n \text{ times}}$. We then extend the notation by letting $[0]P = \infty$ and $[-n]P = [n](-P)$.
Note that we can compute $[n]P$ in $\Theta(\log n)$ group operations using square and multiply.
For $m \in \mathbb{Z}$ we can define a map $[m] : E \to E$ accordingly, and write:

$$E[m] := \ker[m]$$

to be the m-**torsion subgroup** of E.

» Number of Points on a curve

Heuristically, we expect $\approx q + 1$ points

Theorem (Hasse)

Let E be an elliptic curve defined over $\mathbb{F}_q$.

$$|\#E(\mathbb{F}_q) - q - 1| \leq 2\sqrt{q}$$

Exact value can be efficiently found using Schoof's algorithm in $O((\log q)^8)$.

» Discrete Logarithm

Cryptography relies on hardness assumptions.

Definition

Let $\mathrm{Gen}(1^\lambda)$ be a p.p.t. algorithm that returns a group description $\mathbb{G} = (+, P, q)$, where $\mathbb{G} = \langle P \rangle$ and $q = \#\mathbb{G}$. For an attacker $\mathcal{A}$, define

$$\mathsf{Adv}_{\mathcal{A}}^{\mathrm{dlp}}(\lambda) = \Pr\left[\mathcal{A}\left(1^\lambda, \mathbb{G}, [k]P\right) = k \;\middle|\; \begin{array}{c} \mathbb{G} \xleftarrow{\$} \mathrm{Gen}(1^\lambda) \\ k \xleftarrow{\$} \mathbb{Z}_q \end{array}\right]$$

We say that the **discrete logarithm assumption** hold with respect to Gen if, for every p.p.t. attacker $\mathcal{A}$, $\mathsf{Adv}_{\mathcal{A}}^{\mathrm{dlp}}(\cdot)$ is negligible.

» Related Assumptions

In practice, we make stronger assumptions, such as Computational Diffie Hellman and Decisional Diffie Hellman.

* CHD: From $[x]P, [y]P$ compute $[xy]P$
* DDH: Distinguish $(P, [x]P, [y]P, [xy]P)$ from $(P, [x]P, [y]P, [z]P)$

In fact, pairings make DDH easy on elliptic curves!

$$\mathrm{DDH} \leq_R \mathrm{CDH} \leq_R {}^{3}\mathrm{DLP}$$

Representation matters! $\mathbb{Z}_{p-1} \cong \mathbb{Z}_p^*$ as groups but the discrete logarithm is trivial in the former, assumed hard in the latter.

[3] In fact equivalent

» Why elliptic curves?

Assumption	Group	Best Algorithm	$\approx$ Complexity
RSA	$\mathbb{Z}_N$	Number Field Sieve	$\exp(c\sqrt[3]{\log N})$
DLP	$\mathbb{F}_p^*$	Number Field Sieve	$\exp(c\sqrt[3]{\log p})$
DLP	$E(\mathbb{F}_p)$	Pollard Rho	$\sqrt{p}$

Best known attacks against ECC are generic attacks

- Shorter keysizes (≈ 256 vs[4] 3072 bits)
- Faster computation[5]

[4] For 128 bits of security

[5] against other DLP schemes and private RSA ops

» EC Diffie Hellman Key Exchange

Let E be an elliptic curve over $\mathbb{F}_q$. Let p be a large prime dividing $\#E(\mathbb{F}_q)$ and P a point of order p.

Diffie Hellman		
Alice		**Bob**
$x \xleftarrow{\$} \mathbb{Z}_q$		$y \xleftarrow{\$} \mathbb{Z}_q$
$Q_A = [x]P$		$Q_B = [y]P$
	$\xrightarrow{Q_A}$	
	$\xleftarrow{Q_B}$	
$K = [x]Q_B$		$K = [y]Q_A$

Correctness follows since:

$$K = [x]Q_B = [x][y]P = [xy]P = [y][x]P = [y]Q_A = K$$

» Easy Elliptic Curves

DLP is not equally hard on every curve!

- Singular curves over $\mathbb{F}_p$. Equivalent to DLP in[6] $\mathbb{F}_p^*$ or $\mathbb{F}_p^+$
- Curves and subgroups with small embedding degree. E.g. supersingular and anomalous curves
- Curves that admit pairings to small finite fields.
- Curves defined over $\mathbb{F}_{p^k}$ for k with small factors. GHS Method, Diem's Analysis.

[6] Or in some small extension

» Pollard Rho

Collision search for $f : S \to S$. Let $x_0 \in S$, $x_n = f(x_{n-1})$.
TODO: Insert image
Expected $\sqrt{\pi \# S/2}$ calls to f, constant memory.

» Pollard Rho

Let G be a group of order N. We want to find k s.t. $[k]P = Q$. Split $G = A \sqcup B \sqcup C$ with $\#A \approx \#B \approx \#C$. Define

$$f(X) = \begin{cases} P + X, & X \in A \\ [2]X, & X \in B \\ Q + X, & X \in C \end{cases}$$

Let $X_0 = \infty$, then $X_i = [\alpha_i]P + [\beta_i]Q$ and we can track α_i, β_i. A collision $X_j = X_{j+\ell}$ with $\gcd(\beta_{j+\ell} - \beta_j, N) = 1$ allows us to solve the DLP with

$$k \equiv \frac{\alpha_j - \alpha_{j+\ell}}{\beta_{j+\ell} - \beta_j} \pmod N$$

Pairings

Definition

Let $\mathbb{G}, \mathbb{G}_T$ be two groups. A **pairing** is a map $e : \mathbb{G} \times \mathbb{G} \to \mathbb{G}_T$ that is:

* Non degenerate:

$$e(S,T) = 1 \; \forall S \in \mathbb{G} \implies T = 0_{\mathbb{G}}$$

* Bilinear:

$$e(S_1 + S_2, T) = e(S_1, T)e(S_2, T)$$

$$e(S, T_1 + T_2) = e(S, T_1)e(S_2, T_2)$$

* Alternating:

$$e(T,T) = 1$$

» Weil Pairing

Every elliptic curve E over K admits an efficiently computable pairing

$$e_m : E[m] \times E[m] \to \mu_m$$

where μ_m is the group of m-th root of unity.
In degenerate on cyclic subgroups of $E[m]$, so use modified Weil pairing

$$\begin{aligned} \langle \cdot, \cdot \rangle : E[m] \times E[m] &\to \mu_m \\ \langle P, Q \rangle &= e_m(S, \phi(Q)) \end{aligned}$$

For $\phi : E \to E$ a distorsion map[7]

[7] If it exists

» BLS Signatures

Let $\mathbb{G}, \mathbb{G}_T$ be cyclic groups of prime order p. Let P be a generator of $\mathbb{G}$, and e a non degenerate pairing. Also, let $H : \{0,1\}^* \to \mathbb{G}$

$\underline{\mathrm{Gen}(1^\lambda)}$	$\underline{\mathrm{Sign}(sk, m)}$
$x \leftarrow\!\$\ \mathbb{Z}_p$	$Q \leftarrow H(m)$
$pk \coloneqq [x]P$	$\sigma \leftarrow [x]Q$
$sk \coloneqq x$	$\textbf{return}\ \sigma$
$\textbf{return}\ (pk, sk)$	

$\underline{\mathrm{Verify}(pk, m, \sigma)}$

$\textbf{return}\ e(\sigma, P) =_? e(H(m), [x]P)$

Correctness by:

$$e(\sigma, P) = e([x]Q, P) = e(Q, P)^x = e(Q, [x]P) = e(H(m), [x]P)$$

* Yes, lattices, codes, multinear maps...
* **Isogenies!**

» Isogenies

"Nice maps" between elliptic curves.

Definition

Let E_1, E_2 be elliptic curves. An **isogeny** is a morphism

$$\phi : E_1 \to E_2$$

with $\phi(\infty) = \infty$. If $\phi(E_1) \neq \{\infty\}$, E_1 is **isogenous** to E_2.

For example, the curves $y^2 = x^3 + x$ and $y^2 = x^3 - 3x + 3$ are isogenous over $\mathbb{F}_{71}$ via the isogeny

$$(x, y) \mapsto \left(\frac{x^3 - 4x^2 + 30x - 12}{(x-2)^2}, y \cdot \frac{x^3 - 6x^2 - 14x + 35}{(x-2)^3} \right)$$

» Properties of isogenies

* Each isogeny is also a group homomorphism
* The map $[m] : E \to E$ is an isogeny
* You can compose isogenies
* Each isogeny has a degree, and it is multiplicative $\deg(\phi \circ \psi) = \deg(\phi)\deg(\psi)$
* Each isogeny $\phi : E_1 \to E_2$ has a unique dual $\hat{\phi} : E_2 \to E_1$ such that
$$\phi \circ \hat{\phi} = [\deg(\phi)]$$
* An isogeny between two Weierstrass curves has the form
$$(x, y) \mapsto \left(\frac{f}{h^2}(x), y \cdot \frac{g}{h^3}(x)\right)$$

» Separable and Inseparable Isogenies

Definition

Let $E/k : y^2 = x^3 + ax + b$, with $\mathrm{char}(k) = p$. Define $E^{(p^r)} : y^2 = x^3 + a^{p^r}x + b^{p^r}$. The map:

$$\pi : E \to E^{(p^r)}, (x, y) \mapsto \left(x^{p^r}, y^{p^r}\right)$$

is the (p^r)-**Frobenius isogeny**. Note if $k = \mathbb{F}_{p^r}$ then $E^{(p^r)} = E$

If an isogeny factors trough a Frobenius isogeny it is inseparable. We are mostly concerned with the separable case.

» Kernel and Velu

Theorem

There is a one to one correspondence between finite subgroups of elliptic curves and separable isogenies from that curve, up to post-compostion with isomorphisms

$$\textit{kernels} \longleftrightarrow \textit{isogenies}$$

Let E/k, with k a finite field. For any subgroup $H \leq E$ we can find an isogeny with kernel H in $\Theta(\#H)$ using Velu's formulas. We denote the target of that isogeny by E/H

» Computing large degree isogenies

For crypto, we want to compute isogeny of large degree i.e. with large kernels. Velu's formulas are too slow.

» Isogeny Problems

It is easy to find out if two curves are isogenous

Theorem

Two curves E_1, E_2 over a finite field k are isogenous over k if and only if $\#E_1(k) = \#E_2(k)$.

Finding the isogeny is dramatically harder
